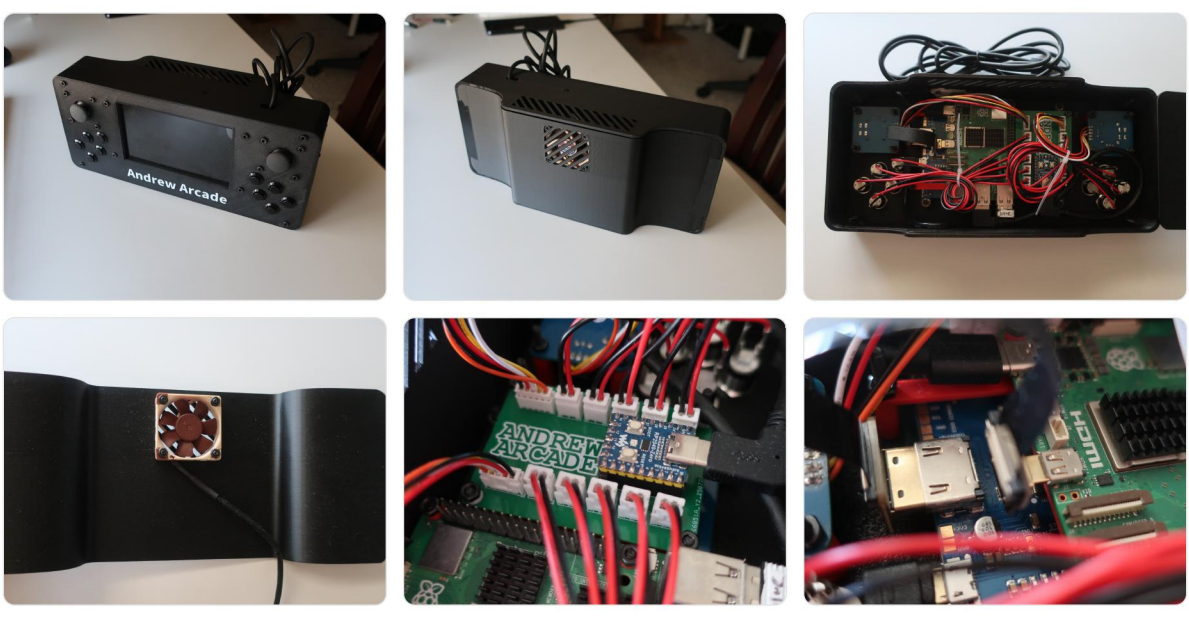
Andrew Arcade

github.com/Andrew-Arcade

A custom game console built on a Raspberry Pi 5 running Linux. Andrew Arcade plays Unity games created by me and other contributors, using Box64 emulation to translate x86 Unity builds to the Pi's ARM architecture. The current version features a redesigned case with improved ergonomics. Future plans include switching to a lighter Linux distribution for better performance and rewriting core apps in Godot, which can be compiled natively for ARM, eliminating the need for emulation.



Oranyth

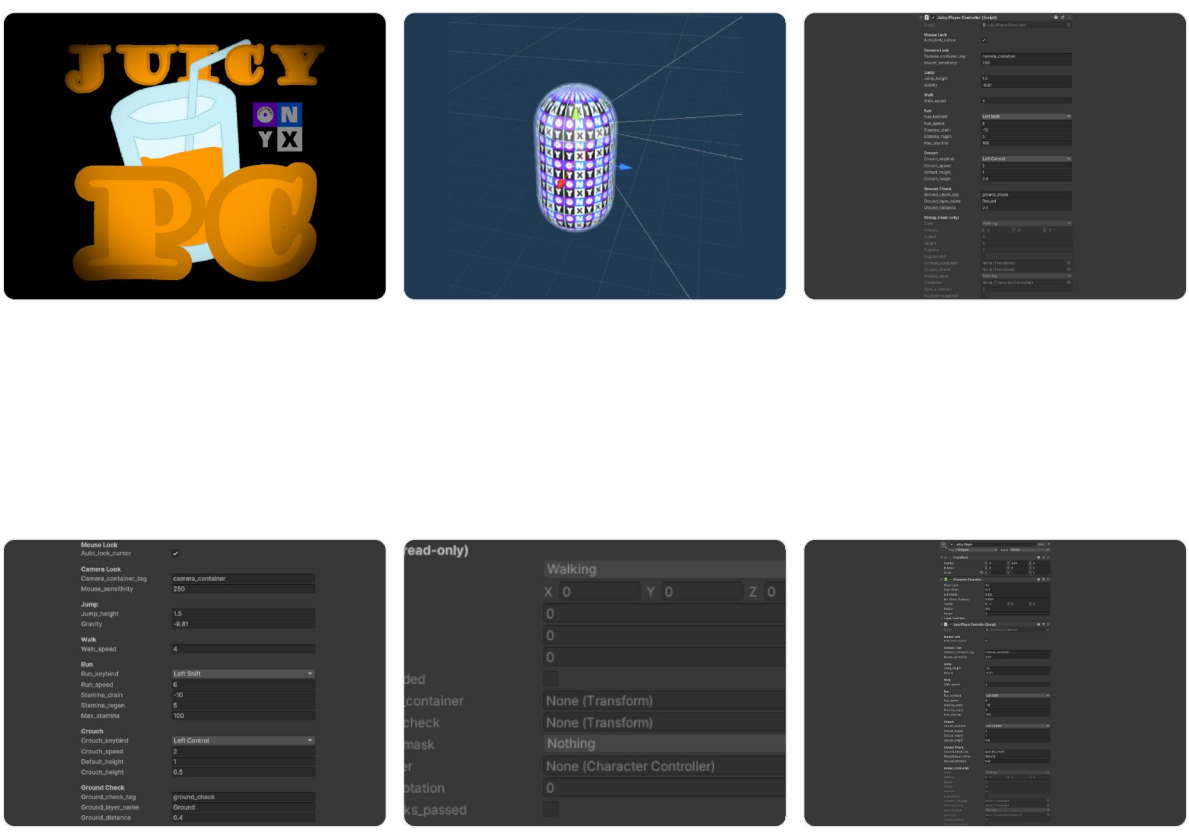
onyx.andrewcromar.org/#oranyth

Oranyth is a fast-paced survival game where players collect dots that match their current color while racing against a constantly decreasing timer. Picking up the correct colors adds time while mistakes reduce it, creating a simple mechanic that becomes increasingly challenging as the game progresses. The game also includes power-ups like time freeze and rainbow that temporarily change the gameplay and strategy.

Juicy Player Controller

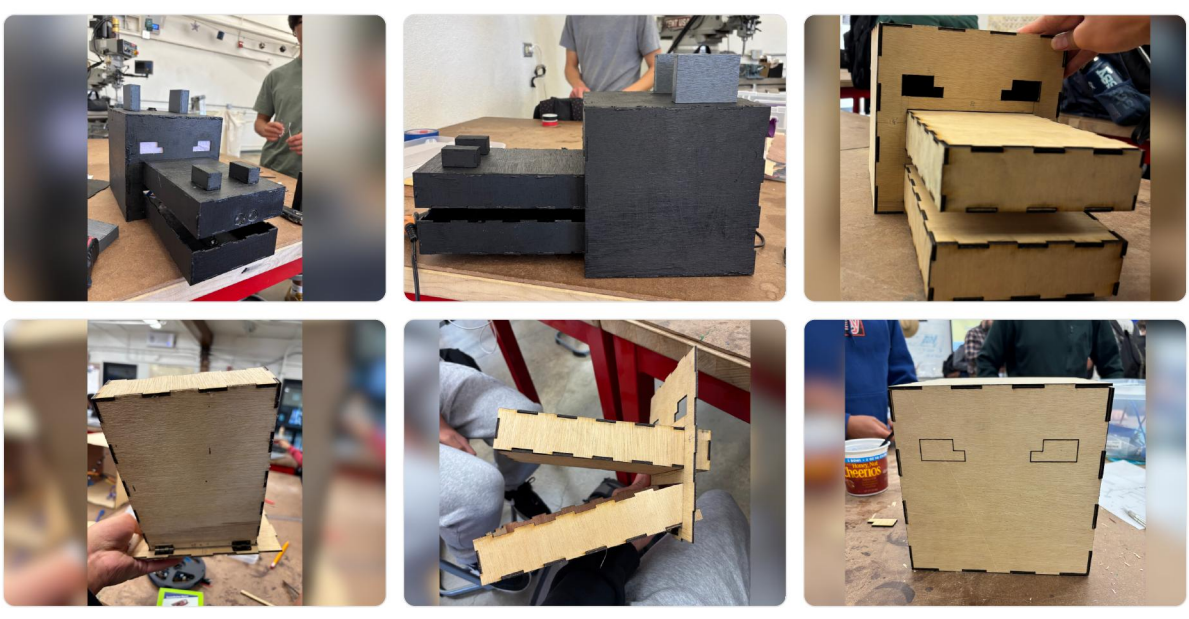
github.com/onyx-development/Juicy-Player-Controller

Juicy Player Controller is a single C# script for Unity 3D that serves as a base player controller for both first-person and third-person games. It comes in two flavors: Orange for first-person and Lemonade for third-person. Features include walking, running, crouching, jumping, a stamina system, camera controls, and cursor management, all fully customizable with sensible defaults and an accessible API. Built on Unity's Input System, it also includes integrated error logging and inspector debugging tools to streamline development.

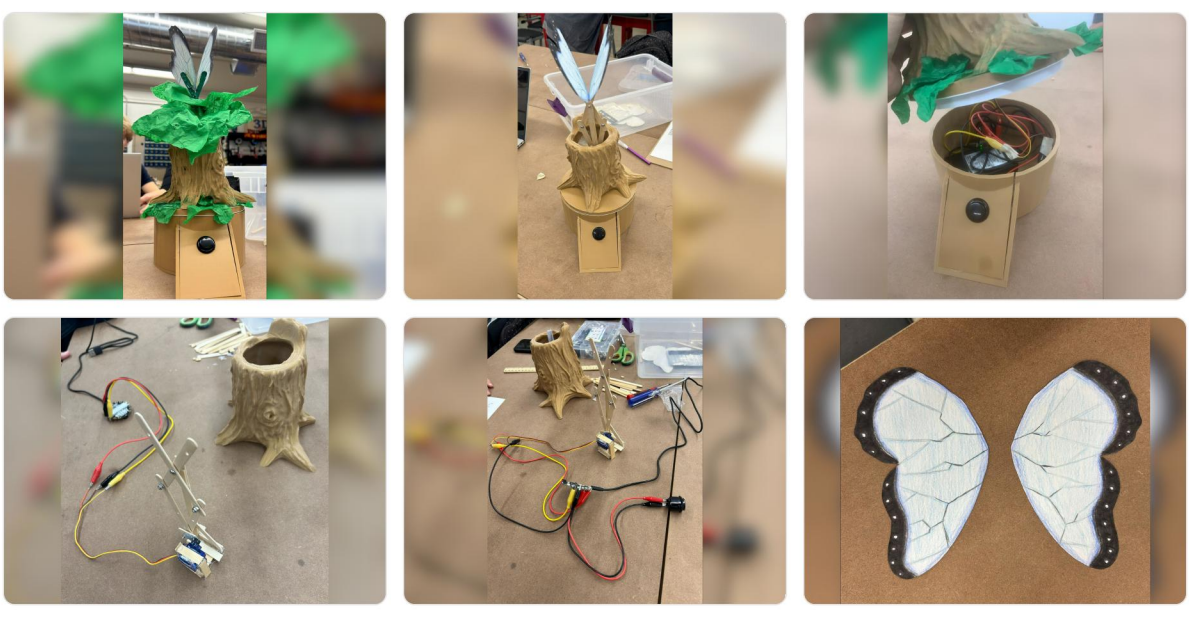


Animatronic Ender Dragon Head

This project was build for my animatronics class. I was in a team of four people, and we worked together to design and build this head. I was responsible for the design and part of the programming. The head features glowing eyes and a mouth that opens and closes. Both these actions are triggered by a ultrasonic sensor in the end of the snout. When someone gets close to the sensor, the eyes light up and the mouth opens. When they move away, the eyes turn off and the mouth closes.



Animatronic Butterfly

For my animatronics class, I worked with two other people to build this animatronic butterfly. I took on designing the popsicle stick scissor


mechanism, the base, and the code. The mechanism connects both wings to a single servo motor, so when someone presses the button, both wings flap together.
